

Hi Debbie,

The first real statistics are coming in from the field research. Through three groups and four sub-groups we are able to extrapolate certain facts regarding the efficacy of ProArgin9 ...

The active group (actually taking ProArgin9 along with mild dietary modifications and exercise 3X weekly) 4.7 lbs per week for 6 weeks on average...three full inches from the waist line on average...30% improvement in BMI

The sham group (taking a powdered vitamin rather than ProArgin9 (disguised in the same container), dietary modifications and exercise 3X weekly) 2.6 lbs per week for 6 weeks on average...1 to 2 inches decreased from waist...little change in BMI after 6 weeks.

Subgroup one was for those who took ProArgin9 but did not modify the diet or exercise regularly...3.2 lbs weight loss per week for 6 weeks on average...2 inches from waist line...15% improvement in BMI

This is substantial! People who did no exercise and ate their normal diet while taking ProArgi9 out-performed subjects who modified their diets and exercised regularly. The obvious and most outrageous improvements took place with the group that modified their diets (no refined sugars or white flour products), took one sccop of Proargin( daily and exercised 3X weekly for a minimum of 30 minutes. It will be another 60 days or so before the alpha group has completed their 90 day cycle (some started 30 to 60 days after the first participants) but the data is quite impressive. When I have enough to give to the statistician for factoring I will give you a full preliminary report.

I wanted to share the news with you. I think this is truly fantastic!  
Talk with you soon!

Dr. Stan
